Fortify Security Report

Aug 1, 2018

dlowe

Executive Summary

Issues Overview

On Aug 1, 2018, a source code review was performed over the Signal Performance Metrics code base. 1,674 files, 60,123 LOC (Executable) were scanned and reviewed for defects that could lead to potential security vulnerabilities. A total of 251 reviewed findings were uncovered during the analysis.

Issues by Fortify Priority Order	
High	234
Critical	17

Recommendations and Conclusions

The Issues Category section provides Fortify recommendations for addressing issues at a generic level. The recommendations for specific fixes can be extrapolated from those generic recommendations by the development group.

Vulnerability Examples by Category

Category: Mass Assignment: Insecure Binder Configuration (50 Issues)

Abstract:

The framework binder used for binding the HTTP request parameters to the model class has not been explicitly configured to allow, or disallow, certain attributes.

Explanation:

To ease development and increase productivity, most modern frameworks allow an object to be automatically instantiated and populated with the HTTP request parameters whose names match an attribute of the class to be bound. Automatic instantiation and population of objects speeds up development, but can lead to serious problems if implemented without caution. Any attribute in the bound classes, or nested classes, will be automatically bound to the HTTP request parameters. Therefore, malicious users will be able to assign a value to any attribute in bound or nested classes, even if they are not exposed to the client through web forms or API contracts.

Example 1: With no additional configuration, the following ASP.NET MVC controller method will bind the HTTP request parameters to any attribute in the RegisterModel or Details classes:

```
public ActionResult Register(RegisterModel model)
{
if (ModelState.IsValid)
{
try
{
return RedirectToAction("Index", "Home");
}
catch (MembershipCreateUserException e)
{
ModelState.AddModelError("", "");
}
}
return View(model);
}
```

Where RegisterModel class is defined as:

```
public class RegisterModel
{
[Required]
[Display(Name = "User name")]
```

```
public string UserName { get; set; }

[Required]
[DataType(DataType.Password)]
[Display(Name = "Password")]
public string Password { get; set; }

[DataType(DataType.Password)]
[Display(Name = "Confirm password")]
public string ConfirmPassword { get; set; }

public Details Details { get; set; }

public RegisterModel()
{
Details = new Details();
}
}
```

and Details class is defined as:

```
public class Details
{
public Details()
{
IsAdmin = false;
}
public bool IsAdmin { get; set; }
...
}
```

Example 2: When using TryUpdateModel() or UpdateModel() in ASP.NET MVC or Web API applications, the model binder will automatically try to bind all HTTP request parameters by default:

```
public ViewResult Register()
{
var model = new RegisterModel();
TryUpdateModel<RegisterModel>(model);
return View("detail", model);
}
```

Example 3: In ASP.NET Web API applications, the model binder will automatically try to bind all HTTP request parameters by default using the configured JSON or XML serializer/deserializer. By default, the binder will try to bind all possible attributes from the HTTP request parameters or body:

```
public class ProductsController : ApiController
{
public string SaveProduct([FromBody] Product p)
{
return p.Name;
}
...
}
```

Example 4: In ASP.NET Web Form applications, the model binder will automatically try to bind all HTTP request parameters when using TryUpdateModel() or UpdateModel() with IValueProvider interface.

```
Employee emp = new Employee();
TryUpdateModel(emp, new System.Web.ModelBinding.FormValueProvider(ModelBindingExecutionContext));
if (ModelState.IsValid)
{
db.SaveChanges();
```

```
}
```

and Employee class is defined as:

```
public class Employee
{
public Employee()
{
IsAdmin = false;
IsManager = false;
}
public string Name { get; set; }
public string Email { get; set; }
public bool IsManager { get; set; }
public bool IsAdmin { get; set; }
}
```

Recommendations:

When using frameworks that provide automatic model binding capabilities, it is a best practice to control which attributes will be bound to the model object so that even if attackers are able to identify other non-exposed attributes of the model or nested classes, they will not be able to bind arbitrary values from HTTP request parameters.

Depending on the framework used there will be different ways to control the model binding process:

Example 5: It is possible to control the ASP.NET MVC model binding process using the [Bind] attribute:

```
[Bind(Exclude = "IsAdmin")]
public class Details
{
public Details()
{
IsAdmin = false;
}
public bool IsAdmin { get; set; }
...
}
```

Example 6: When using TryUpdateModel() or UpdateModel() in ASP.NET MVC or Web API applications, an additional string array can be passed to specify the allowed or disallowed attributes:

```
public ViewResult Register()
{
var model = new RegisterModel();
String[] array = new String[] { "FirstName" };
TryUpdateModel<RegisterModel>(model, array);
return View("detail", model);
}
```

Example 7: In ASP.NET Web API applications, the model classes bound to the HTTP request parameters can be annotated to control the binding process. For example, if the application is using JSON.NET for JSON serialization, the [JsonIgnore] attribute can be used to ignore certain attributes that should not be included in the serialization/deserialization process:

```
public class Details
{
public Details()
{
IsAdmin = false;
}
[JsonIgnore]
public bool IsAdmin { get; set; }
...
```

```
}
```

Example 8: In ASP.NET Web Form applications, this issue can be prevented using appropriate use of [BindNever] attribute, available under System.Web.ModelBinding namespace.

```
public class Employee
{
public Employee()
{
IsAdmin = false;
IsManager = false;
}
public string Name { get; set; }
public string Email { get; set; }

[BindNever]
public bool IsManager { get; set; }
[BindNever]
public bool IsAdmin { get; set; }
}
```
A different approach to protecting against mass assignment vulnerabilities is using a layered architecture where the HTTP request parameters are bound to DTO objects. The DTO objects are only used for that purpose, exposing only those attributes defined in the web forms or API contracts, and then mapping these DTO objects to Domain objects where the rest of the private attributes can be defined.

Tips:

1. This vulnerability category can be classified as a design flaw since accurately finding these issues requires understanding of the application architecture which is beyond the capabilities of static analysis. Therefore, it is possible that if the application is designed to use specific DTO objects for HTTP request binding, there will not be any need to configure the binder to exclude any attributes.

AccountController.cs, line 292 (Mass Assignment: Insecure Binder Configuration)			
Fortify Priority:	High	Folder	High
Kingdom:	API Abuse		
Abstract:	The framework binder used for binding the HTTP request parameters to the model class has not been explicitly configured to allow, or disallow, certain attributes.		

Sink:	AccountController.cs:292 Variable: model()

```
290                    [AllowAnonymous]
291                    [ValidateAntiForgeryToken]
292                    public async Task<ActionResult> Login(LoginViewModel model, string returnUrl)
293                    {
294                        if (returnUrl == null)
```

Analysis:	Bad Practice	
Comments:	*dlowe@utah.gov 2018-08-01 9:33 AM*	This code is from Microsoft. Need to investigate what properties to bind to.

Category: Password Management: Password in Configuration File (48 Issues)

Number of Issues

Abstract:

Storing a plaintext password in a configuration file could result in a system compromise.

Explanation:

Storing a plaintext password in a configuration file allows anyone who can read the file access to the password-protected resource. Developers sometimes believe that they cannot defend the application from someone who has access to the configuration, but this attitude makes an attacker's job easier. Good password management guidelines require that a password never be stored in plaintext.

Recommendations:

A password should never be stored in plaintext. Instead, the password should be entered by an administrator when the system starts. If that approach is impractical, a less secure but often adequate solution is to obfuscate the password and scatter the de-obfuscation material around the system so that an attacker has to obtain and correctly combine multiple system resources to decipher the password.

Microsoft(R) provides a tool that can be used in conjunction with the Windows Data Protection application programming interface (DPAPI) to protect sensitive application entries in configuration files [1].

Tips:

1. HPE Security Fortify Static Code Analyzer searches configuration files for common names used for password properties. Audit these issues by verifying that the flagged entry is used as a password and that the password entry contains plaintext.

2. If the entry in the configuration file is a default password, require that it be changed in addition to requiring that it be obfuscated in the configuration file.

3. The following ASP .NET configuration file appears to contain an encrypted password with the hexadecimal value 0x174f7a68:

<configuration>

...

<appSettings>

<add key="pwd" value="0x174f7a68" />

</appSettings>

...

</configuration>

However, to verify that the password is actually encrypted, you must locate where the password is used in the application code and ensure that an appropriate decryption algorithm is used. If such a function is never called, then the creator of the password may have chosen a hexadecimal value to make the password hard to guess, which means the application is still vulnerable because the password is stored in plaintext.

| App.config, line 8 (Password Management: Password in Configuration File)			
Fortify Priority:	High	**Folder**	High
Kingdom:	Environment		
Abstract:	Storing a plaintext password in a configuration file could result in a system compromise.

         security=True;MultipleActiveResultSets=True;Connection
         Timeout=500;App=EntityFramework" providerName="System.Data.SqlClient" />-->
8              <add name="SPM" connectionString="data source=spmserver;initial
         catalog=MOE_Orig;Persist Security Info=True;User ID=SPM;Password=******
         providerName="System.Data.SqlClient" />
9              <add name="ADConnectionString" connectionString="LDAP://itwcap1" />
10           </connectionStrings>
```

Analysis:	Not an Issue
Comments:	*dlowe@utah.gov 2018-08-01 9:03 AM* These will be encrypted on the production machines

Fortify Security Report

Category: ASP.NET MVC Bad Practices: Optional Submodel With Required Property (39 Issues)

Number of Issues

Chart: Horizontal bar chart with x-axis "Number of Issues" (0.0 to 32.5 in increments of 2.5) and y-axis "Analysis" with categories:
- <Unaudited>
- Not an Issue: ~32
- Reliability Issue
- Bad Practice: ~1
- Suspicious: ~6
- Exploitable

Abstract:

The model class Approach has a required property of which the type is an optional member of a parent model type and therefore may be susceptible to under-posting attacks.

Explanation:

If a model class has required property and is the type of an optional member of a parent model class, it may be susceptible to under-posting attacks if an attacker communicates a request that contains less data than is expected.

The ASP.NET MVC framework will try to bind request parameters to model properties, including submodels.

If a submodel is optional -- that is, the parent model has a property without the [Required] attribute -- and if an attacker does not communicate that submodel, then the parent property will have a null value and the required fields of the child model will not be asserted by model validation. This is one form of an under-posting attack.

Consider the following the model class definitions:

```
public class ChildModel
{
public ChildModel()
{
}
[Required]
public String RequiredProperty { get; set; }
}
public class ParentModel
{
public ParentModel()
{
}
public ChildModel Child { get; set; }
}
```

If an attacker does not communicate a value for the ParentModel.Child property, then the ChildModel.RequiredProperty property will have a [Required] which is not asserted. This may produce unexpected and undesirable results.

Recommendations:

Make the child model field required:

```
public class ChildModel
{
public ChildModel()
{
}
[Required]
```
public String RequiredProperty { get; set; }

}

public class ParentModel

{

public ParentModel()

{

}

[Required]

public ChildModel Child { get; set; }

}

Approach.cs, line 26 (ASP.NET MVC Bad Practices: Optional Submodel With Required Property)

Fortify Priority:	High		Folder	High
Kingdom:	API Abuse			

Abstract:	The model class Approach has a required property of which the type is an optional member of a parent model type and therefore may be susceptible to under-posting attacks.

Sink:	Approach.cs:26 Function: set_ApproachModel()

```
24              public ControllerEventLogs DetectorEvents { get; private set; }
25
26              public Models.Approach ApproachModel { get; set; }
27
28              public void SetDetectorEvents(Models.Approach approach, DateTime startdate,
         DateTime enddate, bool has_pcd,
```

Analysis:	Not an Issue	
Comments:	*dlowe@utah.gov 2018-07-31 1:45 PM*	These relationships are required for either partial views or to define a relationship in entity framework

Category: ASP.NET MVC Bad Practices: Controller Action Not Restricted to POST (35 Issues)

Number of Issues

Abstract:

The controller action in class DataExportController may benefit from being restricted to only accept the POST verb.

Explanation:

ASP.NET MVC controller actions that modify data by writing, updating, or deleting could benefit from being restricted to accept the POST verb. This increases the difficulty of cross-site request forgery because accidental clicking of links will not cause the action to execute.

The following controller action by default accepts any verb and may be susceptible to cross-site request forgery:

public ActionResult UpdateWidget(Model model)

{

// ... controller logic

}

Recommendations:

The following controller action accepts only the POST verb because it has the [HttpPost] attribute:

[HttpPost]

public ActionResult UpdateWidget(Model model)

{

// ... controller logic

}

This approach does not completely protect against cross-site request forgery; sophisticated attackers can still use scripting-based approaches to circumvent this mechanism. However, using this approach increases the difficulty of an attack with very little cost.

DataExportController.cs, line 154 (ASP.NET MVC Bad Practices: Controller Action Not Restricted to POST)			
Fortify Priority:	High	**Folder**	High
Kingdom:	API Abuse		
Abstract:	The controller action in class DataExportController may benefit from being restricted to only accept the POST verb.		
Sink:	DataExportController.cs:154 Function: GetRecordCount()		

```
152                    }
153
154              public ActionResult GetRecordCount(DataExportViewModel dataExportViewModel)
155              {
156                  if (ModelState.IsValid)
```

Analysis:	Not an Issue	
Comments:	*dlowe@utah.gov 2018-07-31 12:56 PM*	This does not update any resources. Not a post method.

Category: ASP.NET MVC Bad Practices: Model With Optional and Required Properties (30 Issues)

Abstract:

The model class AggregateDataExportController has properties that are required and properties that are not required and therefore may be susceptible to over-posting attacks.

Explanation:

Using a model class that has properties that are required (as marked with the [Required] attribute) and properties that are optional (as not marked with the [Required] attribute) can lead to problems if an attacker communicates a request that contains more data than is expected.

The ASP.NET MVC framework will try to bind request parameters to model properties.

Having mixed requiredness without explicitly communicating which parameters are to be model-bound may indicate that there are model properties for internal use but can be controlled by attacker.

The following code defines a possible model class that has properties that have [Required] and properties that do not have [Required]:

```
public class MyModel
{
[Required]
public String UserName { get; set; }

[Required]
public String Password { get; set; }

public Boolean IsAdmin { get; set; }

}
```

If any optional parameters can change the behavior of an application, then an attacker may be able to actually change that behavior by communicating an optional parameter in a request.

Recommendations:

There are a few possible mechanisms to prevent optional binding:

1. Define model classes specific to external communication.

The following code defines a model class where all properties have [Required], and without any optional properties:

```
public class MyRequiredModel
{
[Required]
public String UserName { get; set; }

[Required]
public String Password { get; set; }

}
```

2. Use the [Bind] attribute to control which parameters should be bound to the model object from the request.

The following code defines a possible model class that has properties that have [Required] and properties that do not have [Required] and has the [Bind] attribute to specify which parameters should be bound:

```
[Bind(Include="UserName,Password")]
public class MyModel
{
[Required]
public String UserName { get; set; }

[Required]
public String Password { get; set; }

public Boolean IsAdmin { get; set; }
}
```
The following code applies the [Bind] attribute at the controller action method:

```
[HttpPost]
public ActionResult Login([Bind(Include = "UserName,Password")] MyModel model)
{
// ... controller logic
}
```

AggregateDataExportController.cs, line 90 (ASP.NET MVC Bad Practices: Model With Optional and Required Properties)

Fortify Priority:	High	Folder	High
Kingdom:	API Abuse		
Abstract:	The model class AggregateDataExportController has properties that are required and properties that are not required and therefore may be susceptible to over-posting attacks.		
Sink:	AggregateDataExportController.cs:90 Function: CreateMetric()		

```
88              [HttpPost]
89              [ValidateAntiForgeryToken]
90              public ActionResult CreateMetric(AggDataExportViewModel
         aggDataExportViewModel)
91              {
92                  switch (aggDataExportViewModel.SelectedMetricTypeId)
```

Analysis:	Bad Practice

Category: ASP.NET MVC Bad Practices: Model With Required Non-Nullable Property (22 Issues)

Abstract:

The model class ApplicationEvent has a required non-nullable property and therefore may be susceptible to under-posting attacks.

Explanation:

Using a model class that has non-nullable properties that are required (as marked with the [Required] attribute) can lead to problems if an attacker communicates a request that contains less data than is expected.

The ASP.NET MVC framework will try to bind request parameters to model properties.

If a model has a required non-nullable parameter and an attacker does not communicate that required parameter in a request -- that is, the attacker uses an under-posting attack -- then the property will have the default value (usually zero) which will satisfy the [Required] validation attribute. This may produce unexpected application behavior.

The following code defines a possible model class that has a required enum, which is non-nullable:

```
public enum ArgumentOptions
{
OptionA = 1,
OptionB = 2
}
public class Model
{
[Required]
public String Argument { get; set; }

[Required]
public ArgumentOptions Rounding { get; set; }
}
```

Recommendations:

There are a few possible ways to address this problem:

1. Wrap non-nullable types in a Nullable. If an attacker does not communicate a value, then the property will be null and will not satisfy the [Required] validation attribute.

The following code defines a possible model class that wraps an enum with a Nullable (as with the ? after the type of the property):

```
public enum ArgumentOptions
{
OptionA = 1,
OptionB = 2
}
public class Model
{
[Required]
```

```
public String Argument { get; set; }

[Required]
public ArgumentOptions? Rounding { get; set; }
}
```

2. Define the default value of zero as a safe default or as a known invalid value.

The following code defines a possible model class that has a required enum, which is non-nullable, but has a safe default value:
```
public enum ArgumentOptions
{
Default = 0,
OptionA = 1,
OptionB = 2
}
public class Model
{
[Required]
public String Argument { get; set; }

[Required]
public ArgumentOptions Rounding { get; set; }
}
```

ApplicationEvent.cs, line 20 (ASP.NET MVC Bad Practices: Model With Required Non-Nullable Property)

Fortify Priority:	High		Folder	High
Kingdom:	API Abuse			
Abstract:	The model class ApplicationEvent has a required non-nullable property and therefore may be susceptible to under-posting attacks.			
Sink:	ApplicationEvent.cs:20 Function: set_Timestamp()			

```
18
19                    [Required]
20                    public DateTime Timestamp { get; set; }
21
22                    [Required]
```

Analysis:	Not an Issue
Comments:	*dlowe@utah.gov 2018-08-01 10:41 AM* We do not want nullable dates in the database

Category: Path Manipulation (16 Issues)

Number of Issues

Abstract:

Attackers can control the filesystem path argument to FileStream() at FTPSClient.cs line 737, which allows them to access or modify otherwise protected files.

Explanation:

Path manipulation errors occur when the following two conditions are met:

1. An attacker can specify a path used in an operation on the filesystem.

2. By specifying the resource, the attacker gains a capability that would not otherwise be permitted.

For example, the program may give the attacker the ability to overwrite the specified file or run with a configuration controlled by the attacker.

Example 1: The following code uses input from an HTTP request to create a file name. The programmer has not considered the possibility that an attacker may provide a file name like "..\\..\\Windows\\System32\\krnl386.exe", which will cause the application to delete an important Windows system file.

String rName = Request.Item("reportName");

...

File.delete("C:\\users\\reports\\" + rName);

Example 2: The following code uses input from a configuration file to determine which file to open and echo back to the user. If the program runs with privileges and malicious users can change the configuration file, they can use the program to read any file on the system that ends with the extension ".txt".

sr = new StreamReader(resmngr.GetString("sub")+".txt");

while ((line = sr.ReadLine()) != null) {

Console.WriteLine(line);

}

Recommendations:

The best way to prevent path manipulation is with a level of indirection: create a list of legitimate resource names that a user is allowed to specify, and only allow the user to select from the list. With this approach the input provided by the user is never used directly to specify the resource name.

In some situations this approach is impractical because the set of legitimate resource names is too large or too hard to keep track of. Programmers often resort to blacklisting in these situations. Blacklisting selectively rejects or escapes potentially dangerous characters before using the input. However, any such list of unsafe characters is likely to be incomplete and will almost certainly become out of date. A better approach is to create a whitelist of characters that are allowed to appear in the resource name and accept input composed exclusively of characters in the approved set.
Tips:

1. If the program is performing input validation, satisfy yourself that the validation is correct, and use the HPE Security Fortify Custom Rules Editor to create a cleanse rule for the validation routine.

2. Implementation of an effective blacklist is notoriously difficult. One should be skeptical if validation logic requires blacklisting. Consider different types of input encoding and different sets of metacharacters that might have special meaning when interpreted by different operating systems, databases, or other resources. Determine whether or not the blacklist can be updated easily, correctly, and completely if these requirements ever change.

3. A number of modern web frameworks provide mechanisms for performing validation of user input. ASP.NET Request Validation and WCF are among them. To highlight the unvalidated sources of input, the HPE Security Fortify Secure Coding Rulepacks dynamically re-prioritize the issues reported by HPE Security Fortify Static Code Analyzer by lowering their probability of exploit and providing pointers to the supporting evidence whenever the framework validation mechanism is in use. In case of ASP.NET Request Validation, we also provide evidence for when validation is explicitly disabled. We refer to this feature as Context-Sensitive Ranking. To further assist the HPE Security Fortify user with the auditing process, the HPE Security Fortify Software Security Research group makes available the Data Validation project template that groups the issues into folders based on the validation mechanism applied to their source of input.

FTPSClient.cs, line 737 (Path Manipulation)

Fortify Priority:	Critical	**Folder**	Critical
Kingdom:	Input Validation and Representation		
Abstract:	Attackers can control the filesystem path argument to FileStream() at FTPSClient.cs line 737, which allows them to access or modify otherwise protected files.

Category: Open Redirect (4 Issues)

Number of Issues

Abstract:

The file AccountController.cs passes unvalidated data to an HTTP redirect on line 697. Allowing unvalidated input to control the URL used in a redirect can aid phishing attacks.

Explanation:

Redirects allow web applications to direct users to different pages within the same application or to external sites. Applications utilize redirects to aid in site navigation and, in some cases, to track how users exit the site. Open redirect vulnerabilities occur when a web application redirects clients to any arbitrary URL that can be controlled by an attacker.

Attackers can utilize open redirects to trick users into visiting a URL to a trusted site and redirecting them to a malicious site. By encoding the URL, an attacker can make it more difficult for end-users to notice the malicious destination of the redirect, even when it is passed as a URL parameter to the trusted site. Open redirects are often abused as part of phishing scams to harvest sensitive end-user data.

Example 1: The following code instructs the user's browser to open a URL parsed from the dest request parameter when a user clicks the link.

String redirect = Request["dest"];

Response.Redirect(redirect);

If a victim receives an email instructing the user to follow a link to "http://trusted.example.com/ecommerce/redirect.asp?dest=www.wilyhacker.com", the user might click on the link believing they would be transferred to the trusted site. However, when the user clicks the link, the code above will redirect the browser to "http://www.wilyhacker.com".

Many users have been educated to always inspect URLs they receive in emails to make sure the link specifies a trusted site they know. However, if the attacker encoded the destination url as follows:

"http://trusted.example.com/ecommerce/redirect.asp?dest=%77%69%6C%79%68%61%63%6B%65%72%2E%63%6F%6D"

then even a savvy end-user may be fooled into following the link.

Recommendations:

Unvalidated user input should not be allowed to control the destination URL in a redirect. Instead, use a level of indirection: create a list of legitimate URLs that users are allowed to specify and only allow users to select from the list. With this approach, input provided by users is never used directly to specify a URL for redirects.

Example 2: The following code references an array populated with valid URLs. The link the user clicks passes in the array index that corresponds to the desired URL.

String redirect = Request["dest"];

Int32 strDest = System.Convert.ToInt32(redirect);

if((strDest >= 0) && (strDest <= strURLArray.Length -1))

{

strFinalURL = strURLArray[strDest];

pageContext.forward(strFinalURL);

}

In some situations this approach is impractical because the set of legitimate URLs is too large or too hard to keep track of. In such cases, use a similar approach to restrict the domains that users can be redirected to, which can at least prevent attackers from sending users to malicious external sites.
Tips:

1. A number of modern web frameworks provide mechanisms for performing validation of user input. ASP.NET Request Validation and WCF are among them. To highlight the unvalidated sources of input, the HPE Security Fortify Secure Coding Rulepacks dynamically re-prioritize the issues reported by HPE Security Fortify Static Code Analyzer by lowering their probability of exploit and providing pointers to the supporting evidence whenever the framework validation mechanism is in use. In case of ASP.NET Request Validation, we also provide evidence for when validation is explicitly disabled. We refer to this feature as Context-Sensitive Ranking. To further assist the HPE Security Fortify user with the auditing process, the HPE Security Fortify Software Security Research group makes available the Data Validation project template that groups the issues into folders based on the validation mechanism applied to their source of input.

2. Fortify RTA adds protection against this category.

```

Analysis:	Not an Issue
Comments:	*dlowe@utah.gov 2018-07-31 12:32 PM*	I have changed the code to verify that the return url is a local url.

Fortify Security Report

Category: Password Management: Hardcoded Password (3 Issues)

Abstract:

Hardcoded passwords may compromise system security in a way that cannot be easily remedied.

Explanation:

It is never a good idea to hardcode a password. Not only does hardcoding a password allow all of the project's developers to view the password, it also makes fixing the problem extremely difficult. Once the code is in production, the password cannot be changed without patching the software. If the account protected by the password is compromised, the owners of the system will be forced to choose between security and availability.

Example: The following code uses a hardcoded password to create a network credential:

...

NetworkCredential netCred =

new NetworkCredential("scott", "tiger", domain);

...

This code will run successfully, but anyone who has access to it will have access to the password. Once the program has shipped, there is likely no way to change the network credential user "scott" with a password of "tiger" unless the program is patched. An employee with access to this information could use it to break into the system. Even worse, if attackers have access to the executable for the application they can disassemble the code, which will contain the values of the passwords used.

Recommendations:

Passwords should never be hardcoded and should generally be obfuscated and managed in an external source. Storing passwords in plaintext anywhere on the system allows anyone with sufficient permissions to read and potentially misuse the password.

Microsoft(R) provides a tool that can be used in conjunction with the Windows Data Protection application programming interface (DPAPI) to protect sensitive application entries in configuration files [1].
Tips:

1. When identifying null, empty, or hardcoded passwords, default rules only consider fields and variables that contain the word password. However, the HPE Security Fortify Custom Rules Editor provides the Password Management wizard that makes it easy to create rules for detecting password management issues on custom-named fields and variables.

502                     if (credential == null)
503                         credential = new NetworkCredential(anonUsername, anonPassword);
504
505                     if (timeout != null)
```

Analysis:	Not an Issue

Category: JSON Injection (1 Issues)

Number of Issues

Analysis: <Unaudited>, Not an Issue, Reliability Issue, Bad Practice, Suspicious, Exploitable

Abstract:

On line 111 of DataExportController.cs, the method GetReCaptchaStatus() writes unvalidated input into JSON. This call could allow an attacker to inject arbitrary elements or attributes into the JSON entity.

Explanation:

JSON injection occurs when:

1. Data enters a program from an untrusted source.

2. The data is written to a JSON stream.

Applications typically use JSON to store data or send messages. When used to store data, JSON is often treated like cached data and may potentially contain sensitive information. When used to send messages, JSON is often used in conjunction with a RESTful service and can be used to transmit sensitive information such as authentication credentials.

The semantics of JSON documents and messages can be altered if an application constructs JSON from unvalidated input. In a relatively benign case, an attacker may be able to insert extraneous elements that cause an application to throw an exception while parsing a JSON document or request. In a more serious case, such as that involving JSON injection, an attacker may be able to insert extraneous elements that allow for the predictable manipulation of business critical values within a JSON document or request. In some cases, JSON injection can lead to cross-site scripting or dynamic code evaluation.

Example 1: The following C# code uses JSON.NET to serialize user account authentication information for non-privileged users (those with a role of "default" as opposed to privileged users with a role of "admin") from user-controlled input variables username and password to the JSON file located at C:\user_info.json:

```
...
StringBuilder sb = new StringBuilder();
StringWriter sw = new StringWriter(sb);

using (JsonWriter writer = new JsonTextWriter(sw))
{
writer.Formatting = Formatting.Indented;

writer.WriteStartObject();

writer.WritePropertyName("role");
writer.WriteRawValue("\"default\"");

writer.WritePropertyName("username");
writer.WriteRawValue("\"" + username + "\"");

writer.WritePropertyName("password");
writer.WriteRawValue("\"" + password + "\"");

writer.WriteEndObject();
}

File.WriteAllText(@"C:\user_info.json", sb.ToString());
```

Yet, because the JSON serialization is performed using JsonWriter.WriteRawValue(), the untrusted data in username and password will not be validated to escape JSON-related special characters. This allows a user to arbitrarily insert JSON keys, possibly changing the structure of the serialized JSON. In this example, if the non-privileged user mallory with password Evil123! were to append ","role":"admin to her username when entering it at the prompt that sets the value of the username variable, the resulting JSON saved to C:\user_info.json would be:

```
{
"role":"default",
"username":"mallory",
"role":"admin",
"password":"Evil123!"
}
```

If this serialized JSON file were then deserialized to a Dictionary object with JsonConvert.DeserializeObject() as so:

String jsonString = File.ReadAllText(@"C:\user_info.json");

Dictionary<string, string> userInfo = JsonConvert.DeserializeObject<Dictionary<string, strin>>(jsonString);

The resulting values for the username, password, and role keys in the Dictionary object would be mallory, Evil123!, and admin respectively. Without further verification that the deserialized JSON values are valid, the application will incorrectly assign user mallory "admin" privileges.

Recommendations:

When writing user supplied data to JSON some guidelines should be followed:

1. Don't create JSON attributes whose names are derived from user input.

2. Ensure that all serialization to JSON is performed using a safe serialization function that delimits untrusted data within single or double quotes and escapes any special characters.

Example 2: The following C# code implements the same functionality as that in Example 1, but instead uses JsonWriter.WriteValue() rather than JsonWriter.writeRawValue() to serialize the data, therefore ensuring that any untrusted data is properly delimited and escaped:

...

StringBuilder sb = new StringBuilder();
StringWriter sw = new StringWriter(sb);

using (JsonWriter writer = new JsonTextWriter(sw))
{
writer.Formatting = Formatting.Indented;

writer.WriteStartObject();

writer.WritePropertyName("role");
writer.WriteValue("default");

writer.WritePropertyName("username");
writer.WriteValue(username);

writer.WritePropertyName("password");
writer.WriteValue(password);

writer.WriteEndObject();
}

File.WriteAllText(@"C:\user_info.json", sb.ToString());

Reliability Issue

Bad Practice

Suspicious

Exploitable

Abstract:

The method HandleCmd() in FTPSClient.cs mishandles confidential information, which can compromise user privacy and is often illegal.

Explanation:

Privacy violations occur when:

1. Private user information enters the program.

2. The data is written to an external location, such as the console, file system or network.

Example: The following code contains a logging statement that tracks the contents of records added to a database by storing them in a log file. Among other values that are stored, the getPassword() function returns the user-supplied plaintext password associated with the account.

pass = GetPassword();

...

dbmsLog.WriteLine(id+":"+pass+":"+type+":"+tstamp);

The code in the example above logs a plaintext password to the filesystem. Although many developers trust the filesystem as a safe storage location for data, it should not be trusted implicitly, particularly when privacy is a concern.

Private data can enter a program in a variety of ways:

- Directly from the user in the form of a password or personal information

- Accessed from a database or other data store by the application

- Indirectly from a partner or other third party

Sometimes data that is not labeled as private can have a privacy implication in a different context. For example, student identification numbers are usually not considered private because there is no explicit and publicly-available mapping to an individual student's personal information. However, if a school generates identification numbers based on student social security numbers, then the identification numbers should be considered private.

Security and privacy concerns often seem to compete with each other. From a security perspective, you should record all important operations so that any anomalous activity can later be identified. However, when private data is involved, this practice can create risk.

Although there are many ways in which private data can be handled unsafely, a common risk stems from misplaced trust. Programmers often trust the operating environment in which a program runs, and therefore believe that it is acceptable to store private information on the file system, in the registry, or in other locally-controlled resources. However, even if access to certain resources is restricted, this does not guarantee that the individuals who do have access can be trusted. For example, in 2004, an unscrupulous employee at AOL sold approximately 92 million private customer e-mail addresses to a spammer marketing an offshore gambling web site [1].

In response to such high-profile exploits, the collection and management of private data is becoming increasingly regulated. Depending on its location, the type of business it conducts, and the nature of any private data it handles, an organization may be required to comply with one or more of the following federal and state regulations:

- Safe Harbor Privacy Framework [3]

- Gramm-Leach Bliley Act (GLBA) [4]

- Health Insurance Portability and Accountability Act (HIPAA) [5]

- California SB-1386 [6]

Despite these regulations, privacy violations continue to occur with alarming frequency.

Recommendations:

When security and privacy demands clash, privacy should usually be given the higher priority. To accomplish this and still maintain required security information, cleanse any private information before it exits the program.

To enforce good privacy management, develop and strictly adhere to internal privacy guidelines. The guidelines should specifically describe how an application should handle private data. If your organization is regulated by federal or state law, ensure that your privacy guidelines are sufficiently strenuous to meet the legal requirements. Even if your organization is not regulated, you must protect private information or risk losing customer confidence.

The best policy with respect to private data is to minimize its exposure. Applications, processes, and employees should not be granted access to any private data unless the access is required for the tasks that they are to perform. Just as the principle of least privilege dictates that no operation should be performed with more than the necessary privileges, access to private data should be restricted to the smallest possible group.
Tips:

1. As part of any thorough audit for privacy violations, ensure that custom rules have been written to identify all sources of private or otherwise sensitive information entering the program. Most sources of private data cannot be identified automatically. Without custom rules, your check for privacy violations is likely to be substantially incomplete.

2. A number of modern web frameworks provide mechanisms for performing validation of user input. ASP.NET Request Validation and WCF are among them. To highlight the unvalidated sources of input, the HPE Security Fortify Secure Coding Rulepacks dynamically re-prioritize the issues reported by HPE Security Fortify Static Code Analyzer by lowering their probability of exploit and providing pointers to the supporting evidence whenever the framework validation mechanism is in use. In case of ASP.NET Request Validation, we also provide evidence for when validation is explicitly disabled. We refer to this feature as Context-Sensitive Ranking. To further assist the HPE Security Fortify user with the auditing process, the HPE Security Fortify Software Security Research group makes available the Data Validation project template that groups the issues into folders based on the validation mechanism applied to their source of input.

Analysis:	Bad Practice
Comments:	*dlowe@utah.gov 2018-07-31 12:51 PM*	This code was downloaded through Microsoft NUGET. The program that uses ftps is a scheduled task command line tool. This runs behind a firewall and is not accessible to the outside world. Also the program does not use this specific function.

Category: Privacy Violation: Heap Inspection (1 Issues)

Number of Issues

0.0 0.1 0.2 0.3 0.4 0.5 0.6 0.7 0.8 0.9 1.0

Analysis:
- <Unaudited>
- Not an Issue
- Reliability Issue
- Bad Practice
- Suspicious
- Exploitable

Abstract:

The method Main() in Program.cs stores sensitive data in an insecure manner, making it possible to extract the data via inspecting the heap.

Explanation:

Sensitive data (such as passwords, social security numbers, credit card numbers etc.) stored in memory can be leaked if it is stored in a managed String object. String objects are not pinned, so the garbage collector can relocate these objects at will and leave several copies in memory. These objects are not encrypted by default, so anyone that can read the process' memory will be able to see the contents. Furthermore, if the process' memory gets swapped out to disk, the unencrypted contents of the string will be written to a swap file. Lastly, since String objects are immutable, removing the value of a String from memory can only be done by the CLR garbage collector. The garbage collector is not required to run unless the CLR is low on memory, so there is no guarantee as to when garbage collection will take place. In the event of an application crash, a memory dump of the application might reveal sensitive data.

Example 1: The following method returns a password from the console and stores it in an insecure String object.

```
public static String getPassword() {
String inputPassword = "";
ConsoleKeyInfo nextKey = Console.ReadKey(true);
while (nextKey.Key != Console.ReadKey(true)) {
inputPassword.AppendChar(nextKey.KeyChar);
Console.Write("*");
nextKey = Console.ReadKey(true);
}
return inputPassword;
}
```

Recommendations:

Instead of storing sensitive data in objects like Strings, store them in a SecureString object. Each object stores its contents in an encrypted format in memory at all times.
Example 2: The following method returns a password from the console and stores it in a SecureString object.

```
public static SecureString getPassword() {
SecureString inputPassword = new SecureString();
ConsoleKeyInfo nextKey = Console.ReadKey(true);
while (nextKey.Key != Console.ReadKey(true)) {
inputPassword.AppendChar(nextKey.KeyChar);
Console.Write("*");
nextKey = Console.ReadKey(true);
}
inputPassword.MakeReadOnly();
return inputPassword;
}
```

Program.cs, line 64 (Privacy Violation: Heap Inspection)

Fortify Priority:	High		Folder	High
Kingdom:	Security Features			

Abstract:	The method Main() in Program.cs stores sensitive data in an insecure manner, making it possible to extract the data via inspecting the heap.

Source: SignalFTPInfo.cs:9 Read this.Password()

```
7                    public string Secondary_Name { get; set; }
8                    public string User_Name { get; set; }
9                    public string Password { get; set; }
10                   public string FTP_Directory { get; set; }
11                   public string IP_Address { get; set; }
```

Sink: Program.cs:64 Assignment to password()

```
62                        //foreach (char c in row.Password)
63                        //    password.AppendChar(c);
64                        string password =******
65                        string localDir = hostDir + signal.SignalId + "\\";
66                        string remoteDir = row.FTP_Directory;
```

Analysis:	Suspicious
Comments:	*dlowe@utah.gov 2018-08-01 9:31 AM*

This could be a possible issue. This program does run behind the firewall and does not directly receive input from a user. I am unsure at this time how to handle this at the FTP level without exposing the password when I have to convert it to a string.

Category: SQL Injection (1 Issues)

Abstract:

On line 148 of Program.cs, the method UpdateMigrationsTable() invokes a SQL query built using input coming from an untrusted source. This call could allow an attacker to modify the statement's meaning or to execute arbitrary SQL commands.

Explanation:

SQL injection errors occur when:

1. Data enters a program from an untrusted source.

2. The data is used to dynamically construct a SQL query.

Example 1: The following code dynamically constructs and executes a SQL query that searches for items matching a specified name. The query restricts the items displayed to those where owner matches the user name of the currently-authenticated user.

...
string userName = ctx.getAuthenticatedUserName();

string query = "SELECT * FROM items WHERE owner = '"

+ userName + "' AND itemname = '"

+ ItemName.Text + "'";

sda = new SqlDataAdapter(query, conn);

DataTable dt = new DataTable();

sda.Fill(dt);

...

The query that this code intends to execute follows:

SELECT * FROM items
WHERE owner = <userName>
AND itemname = <itemName>;

However, because the query is constructed dynamically by concatenating a constant base query string and a user input string, the query only behaves correctly if itemName does not contain a single-quote character. If an attacker with the user name wiley enters the string "name' OR 'a'='a" for itemName, then the query becomes the following:

SELECT * FROM items
WHERE owner = 'wiley'
AND itemname = 'name' OR 'a'='a';

The addition of the OR 'a'='a' condition causes the where clause to always evaluate to true, so the query becomes logically equivalent to the much simpler query:

SELECT * FROM items;

This simplification of the query allows the attacker to bypass the requirement that the query only return items owned by the authenticated user; the query now returns all entries stored in the items table, regardless of their specified owner.

Example 2: This example examines the effects of a different malicious value passed to the query constructed and executed in Example 1. If an attacker with the user name wiley enters the string "name'); DELETE FROM items; --" for itemName, then the query becomes the following two queries:

SELECT * FROM items

WHERE owner = 'wiley'

AND itemname = 'name';

DELETE FROM items;

--'

Many database servers, including Microsoft(R) SQL Server 2000, allow multiple SQL statements separated by semicolons to be executed at once. While this attack string results in an error on Oracle and other database servers that do not allow the batch-execution of statements separated by semicolons, on databases that do allow batch execution, this type of attack allows the attacker to execute arbitrary commands against the database.

Notice the trailing pair of hyphens (--), which specifies to most database servers that the remainder of the statement is to be treated as a comment and not executed [4]. In this case the comment character serves to remove the trailing single-quote left over from the modified query. On a database where comments are not allowed to be used in this way, the general attack could still be made effective using a trick similar to the one shown in Example 1. If an attacker enters the string "name'); DELETE FROM items; SELECT * FROM items WHERE 'a'='a", the following three valid statements will be created:

SELECT * FROM items

WHERE owner = 'wiley'

AND itemname = 'name';

DELETE FROM items;

SELECT * FROM items WHERE 'a'='a';

One traditional approach to preventing SQL injection attacks is to handle them as an input validation problem and either accept only characters from a whitelist of safe values or identify and escape a blacklist of potentially malicious values. Whitelisting can be a very effective means of enforcing strict input validation rules, but parameterized SQL statements require less maintenance and can offer more guarantees with respect to security. As is almost always the case, blacklisting is riddled with loopholes that make it ineffective at preventing SQL injection attacks. For example, attackers can:

- Target fields that are not quoted

- Find ways to bypass the need for certain escaped meta-characters

- Use stored procedures to hide the injected meta-characters

Manually escaping characters in input to SQL queries can help, but it will not make your application secure from SQL injection attacks.

Another solution commonly proposed for dealing with SQL injection attacks is to use stored procedures. Although stored procedures prevent some types of SQL injection attacks, they fail to protect against many others. Stored procedures typically help prevent SQL injection attacks by limiting the types of statements that can be passed to their parameters. However, there are many ways around the limitations and many interesting statements that can still be passed to stored procedures. Again, stored procedures can prevent some exploits, but they will not make your application secure against SQL injection attacks.

Recommendations:

The root cause of a SQL injection vulnerability is the ability of an attacker to change context in the SQL query, causing a value that the programmer intended to be interpreted as data to be interpreted as a command instead. When a SQL query is constructed, the programmer knows what should be interpreted as part of the command and what should be interpreted as data. Parameterized SQL statements can enforce this behavior by disallowing data-directed context changes and preventing nearly all SQL injection attacks. Parameterized SQL statements are constructed using strings of regular SQL, but when user-supplied data needs to be included, they create bind parameters, which are placeholders for data that is subsequently inserted. Bind parameters allow the program to explicitly specify to the database what should be treated as a command and what should be treated as data. When the program is ready to execute a statement, it specifies to the database the runtime values to use for the value of each of the bind parameters, without the risk of the data being interpreted as commands.

The previous example can be rewritten to use parameterized SQL statements (instead of concatenating user supplied strings) as follows:

...
string userName = ctx.getAuthenticatedUserName();

conn = new SqlConnection(_ConnectionString);

conn.Open();

SqlCommand query = new SqlCommand(

"SELECT * FROM items WHERE itemname=@ItemName

AND owner=@OwnerName", conn);

query.Parameters.AddWithValue("@ItemName", ItemName.Text);

query.Parameters.AddWithValue("@OwnerName", userName);

SqlDataReader objReader = objCommand.ExecuteReader();

...

More complicated scenarios, often found in report generation code, require that user input affect the command structure of the SQL statement, such as the addition of dynamic constraints in the WHERE clause. Do not use this requirement to justify concatenating user input into query strings. Prevent SQL injection attacks where user input must affect statement command structure with a level of indirection: create a set of legitimate strings that correspond to different elements you might include in a SQL statement. When constructing a statement, use input from the user to select from this set of application-controlled values.

Use bind parameters whenever input data must be directly included in a statement.

Tips:

1. A common mistake is to use parameterized SQL statements that are constructed by concatenating user-controlled strings. Of course, this defeats the purpose of using parameterized SQL statements. If you are not certain that the strings used to form statements are constants controlled by the application, do not assume that they are safe because they are not being executed directly as SQL strings. Thoroughly investigate all uses of user-controlled strings in SQL statements and verify that none can be used to modify the meaning of the query.

2. A number of modern web frameworks provide mechanisms for performing validation of user input. ASP.NET Request Validation and WCF are among them. To highlight the unvalidated sources of input, the HPE Security Fortify Secure Coding Rulepacks dynamically re-prioritize the issues reported by HPE Security Fortify Static Code Analyzer by lowering their probability of exploit and providing pointers to the supporting evidence whenever the framework validation mechanism is in use. In case of ASP.NET Request Validation, we also provide evidence for when validation is explicitly disabled. We refer to this feature as Context-Sensitive Ranking. To further assist the HPE Security Fortify user with the auditing process, the HPE Security Fortify Software Security Research group makes available the Data Validation project template that groups the issues into folders based on the validation mechanism applied to their source of input.

3. Fortify RTA adds protection against this category.

Program.cs, line 148 (SQL Injection)

Fortify Priority:	Critical		Folder	Critical
Kingdom:	Input Validation and Representation			
Abstract:	On line 148 of Program.cs, the method UpdateMigrationsTable() invokes a SQL query built using input coming from an untrusted source. This call could allow an attacker to modify the statement's meaning or to execute arbitrary SQL commands.			

Source: Program.cs:124 System.Data.SqlClient.SqlCommand.ExecuteReader()

```
122                    var command = new SqlCommand(sqlQuery, sqlconn);
123
124                    var reader = command.ExecuteReader();
125
126                if (!reader.HasRows)
```

Sink: Program.cs:148 System.Data.SqlClient.SqlCommand.set_CommandText()

```
146                    updateCommand.Connection.Open();
147
148                        updateCommand.CommandText = "update __MigrationHistory set
       MigrationId = '" + newMigrationName +
149                                              "' where MigrationId = '" +
       migrationName + "'";
```

Analysis:	Not an Issue	
Comments:	*dlowe@utah.gov 2018-07-31 12:53 PM*	This is reading its input from the database, not from a user.

External Metadata:

Version: 2016.2.0.0007

Name: CWE

ID: 3ADB9EE4-5761-4289-8BD3-CBFCC593EBBC

The Common Weakness Enumeration (CWE), co-sponsored and maintained by MITRE, is international in scope and free for public use. CWE provides a unified, measurable set of software weaknesses that is enabling more effective discussion, description, selection, and use of software security tools and services that can find these weaknesses in source code and operational systems as well as better understanding and management of software weaknesses related to architecture and design.

Name: FISMA

ID: B40F9EE0-3824-4879-B9FE-7A789C89307C

The Federal Information Processing Standard (FIPS) 200 document is part of the official series of publications, issued by the National Institute of Standards and Technology (NIST), relating to standards and guidelines adopted and promulgated under the provisions of the Federal Information Security Management Act (FISMA). Specifically, FIPS Publication 200 specifies the "Minimum Security Requirements for Federal Information and Information Systems."

Name: NIST SP 800-53 Rev.4

ID: 1114583B-EA24-45BE-B7F8-B61201BACDD0

NIST Special Publication 800-53 Revision 4 provides a list of security and privacy controls designed to protect federal organizations and information systems from security threats. The following table summarizes the number of issues identified across the different controls and broken down by Fortify Priority Order.

Name: OWASP Mobile 2014

ID: EEE3F9E7-28D6-4456-8761-3DA56C36F4EE

The OWASP Mobile Top 10 Risks 2014 provides a powerful awareness document for mobile application security. The OWASP Mobile Top 10 represents a broad consensus about what the most critical mobile application security flaws are. Project members include a variety of security experts from around the world who have shared their expertise to produce this list.

Name: OWASP Top 10 2004

ID: 771C470C-9274-4580-8556-C023E4D3ADB4

The OWASP Top Ten 2004 provides a powerful awareness document for web application security. The OWASP Top Ten represents a broad consensus about what the most critical web application security flaws are. Project members include a variety of security experts from around the world who have shared their expertise to produce this list.

Name: OWASP Top 10 2007

ID: 1EB1EC0E-74E6-49A0-BCE5-E6603802987A

The OWASP Top Ten 2007 provides a powerful awareness document for web application security. The OWASP Top Ten represents a broad consensus about what the most critical web application security flaws are. Project members include a variety of security experts from around the world who have shared their expertise to produce this list.

Name: OWASP Top 10 2010

ID: FDCECA5E-C2A8-4BE8-BB26-76A8ECD0ED59

The OWASP Top Ten 2010 provides a powerful awareness document for web application security. The OWASP Top Ten represents a broad consensus about what the most critical web application security flaws are. Project members include a variety of security experts from around the world who have shared their expertise to produce this list.

Name: OWASP Top 10 2013

ID: 1A2B4C7E-93B0-4502-878A-9BE40D2A25C4

The OWASP Top Ten 2013 provides a powerful awareness document for web application security. The OWASP Top Ten represents a broad consensus about what the most critical web application security flaws are. Project members include a variety of security experts from around the world who have shared their expertise to produce this list.

Name: PCI 1.1

ID: CBDB9D4D-FC20-4C04-AD58-575901CAB531

The Payment Card Industry (PCI) Data Security Standard (DSS) 1.1 compliance standard describes 12 requirements which are organized into 6 logically related groups, which are "control objectives". PCI DSS requirements are applicable if Primary Account Number (PAN) is stored, processed, or transmitted by the system.

Name: PCI 1.2

ID: 57940BDB-99F0-48BF-BF2E-CFC42BA035E5

Payment Card Industry Data Security Standard Version 1.2 description

Name: PCI 2.0

ID: 8970556D-7F9F-4EA7-8033-9DF39D68FF3E

The PCI DSS 2.0 compliance standard, particularly sections 6.3, 6.5, and 6.6, references the OWASP Top 10 vulnerability categories as the core categories that must be tested for and remediated. The following table summarizes the number of issues identified across the different PCI DSS requirements and broken down by Fortify Priority Order.

Name: PCI 3.0

ID: E2FB0D38-0192-4F03-8E01-FE2A12680CA3

The following is a summary of the application security portions of Payment Card Industry (PCI) Data Security Standard (DSS) v3.0. HPE Security Fortify tests for 32 application security related requirements across sections 1, 2, 3, 4, 6, 7, 8, and 10 of PCI DSS and reports whether each requirement is In Place or Not In Place to indicate whether requirements are satisfied or not. This report is intended to measure the level of adherence the specific application(s) possess when compared to PCI DSS 3.0 compliance and is not intended to serve as a comprehensive Report on Compliance (ROC). The information contained in this report is targeted at project managers, security auditors, and compliance auditors.

Name: PCI 3.1

ID: AC0D18CF-C1DA-47CF-9F1A-E8EC0A4A717E

The following is a summary of the application security portions of Payment Card Industry (PCI) Data Security Standard (DSS) v3.1. HPE Security Fortify tests for 31 application security related requirements across sections 1, 2, 3, 4, 6, 7, 8, and 10 of PCI DSS and reports whether each requirement is In Place or Not In Place to indicate whether requirements are satisfied or not. This report is intended to measure the level of adherence the specific application(s) possess when compared to PCI DSS 3.1 compliance and is not intended to serve as a comprehensive Report on Compliance (ROC). The information contained in this report is targeted at project managers, security auditors, and compliance auditors.

Name: PCI 3.2

ID: 4E8431F9-1BA1-41A8-BDBD-087D5826751A

The following is a summary of the application security portions of Payment Card Industry (PCI) Data Security Standard (DSS) v3.2. HPE Security Fortify tests for 31 application security related requirements across sections 1, 2, 3, 4, 6, 7, 8, and 10 of PCI DSS and reports whether each requirement is In Place or Not In Place to indicate whether requirements are satisfied or not. This report is intended to measure the level of adherence the specific application(s) possess when compared to PCI DSS 3.2 compliance and is not intended to serve as a comprehensive Report on Compliance (ROC). The information contained in this report is targeted at project managers, security auditors, and compliance auditors.

Name: SANS Top 25 2009

ID: 939EF193-507A-44E2-ABB7-C00B2168B6D8

The 2009 CWE/SANS Top 25 Programming Errors list the most significant programming errors that can lead to serious software

vulnerabilities. They occur frequently, are often easy to find, and easy to exploit. They are dangerous because they will frequently allow attackers to completely take over the software, steal data, or prevent the software from working at all. The list is the result of collaboration between the SANS Institute, MITRE, and many top software security experts.

Name: SANS Top 25 2010
ID: 72688795-4F7B-484C-88A6-D4757A6121CA
SANS Top 25 2010 Most Dangerous Software Errors provides an enumeration of the most widespread and critical errors, categorized by Common Weakness Enumeration (CWE) identifiers, that lead to serious vulnerabilities in software (http://cwe.mitre.org/). These software errors are often easy to find and exploit. The inherent danger in these errors is that they can allow an attacker to completely take over the software, steal data, or prevent the software from working at all.

Name: SANS Top 25 2011
ID: 92EB4481-1FD9-4165-8E16-F2DE6CB0BD63
SANS Top 25 2011 Most Dangerous Software Errors provides an enumeration of the most widespread and critical errors, categorized by Common Weakness Enumeration (CWE) identifiers, that lead to serious vulnerabilities in software (http://cwe.mitre.org/). These software errors are often easy to find and exploit. The inherent danger in these errors is that they can allow an attacker to completely take over the software, steal data, or prevent the software from working at all.

Name: STIG 3.1
ID: F2FA57EA-5AAA-4DDE-90A5-480BE65CE7E7
Security Technical Implementation Guide Version 3.1 description

Name: STIG 3.10
ID: 788A87FE-C9F9-4533-9095-0379A9B35B12
Each requirement or recommendation identified by the DISA STIG is represented by a STIG identifier (STIGID) which corresponds to a checklist item and a severity code [APP<I>ID</I>: CAT <I>SEV</I>]. DISA STIG defines three severities with respect to vulnerabilities where their:

<LI>exploitation leads to direct and immediate loss of Confidentiality, Availability, or Integrity (CAT I).</LI>
<LI>exploitation potentially results in loss of Confidentiality, Availability, or Integrity (CAT II).</LI>
<LI>existence degrades protections against loss of Confidentiality, Availability, or Integrity (CAT III).</LI> </UL>

The following table summarizes the number of issues identified across the different STIGIDs broken down by Fortify Priority Order. The status of a STIGID is considered "In Place" when there are no issues reported for a given STIGID.

If the project is missing an HPE Security Fortify Static Code Analyzer (SCA) scan, or the scan contains findings that have not been fixed, hidden or suppressed, STIGID APP5080: CAT II is not considered "In Place". Similarly, if the project is missing an HPE Security Fortify WebInspect scan, or the scan contains any critical findings, STIGID APP5100: CAT II is not considered "In Place".

Name: STIG 3.4
ID: 58E2C21D-C70F-4314-8994-B859E24CF855
Each requirement or recommendation identified by the DISA STIG is represented by a STIG identifier (STIGID) which corresponds to a checklist item and a severity code [APP<I>ID</I>: CAT <I>SEV</I>]. DISA STIG identifies several severities with respect to vulnerabilities:

<LI>CAT I: allow an attacker immediate access into a machine, allow super user access, or bypass a firewall.</LI>
<LI>CAT II: provide information that have a high potential of giving access to an intruder.</LI>
<LI>CAT III: provide information that potentially could lead to compromise.</LI> </UL>

The following table summarizes the number of issues identified across the different STIGIDs broken down by Fortify Priority

Order. The status of a STIGID is considered "In Place" when there are no issues reported for a given STIGID.

Name: STIG 3.5

ID: DD18E81F-3507-41FA-9DFA-2A9A15B5479F

Each requirement or recommendation identified by the DISA STIG is represented by a STIG identifier (STIGID) which corresponds to a checklist item and a severity code [APP<I>ID</I>: CAT <I>SEV</I>]. DISA STIG identifies several severities with respect to vulnerabilities:

<LI>CAT I: allow an attacker immediate access into a machine, allow super user access, or bypass a firewall.</LI>
<LI>CAT II: provide information that have a high potential of giving access to an intruder.</LI>
<LI>CAT III: provide information that potentially could lead to compromise.</LI> </UL>

The following table summarizes the number of issues identified across the different STIGIDs broken down by Fortify Priority Order. The status of a STIGID is considered "In Place" when there are no issues reported for a given STIGID.

Name: STIG 3.6

ID: 000CA760-0FED-4374-8AA2-6FA3968A07B1

Each requirement or recommendation identified by the DISA STIG is represented by a STIG identifier (STIGID) which corresponds to a checklist item and a severity code [APP<I>ID</I>: CAT <I>SEV</I>]. DISA STIG identifies several severities with respect to vulnerabilities:

<LI>CAT I: allow an attacker immediate access into a machine, allow super user access, or bypass a firewall.</LI>
<LI>CAT II: provide information that have a high potential of giving access to an intruder.</LI>
<LI>CAT III: provide information that potentially could lead to compromise.</LI> </UL>

The following table summarizes the number of issues identified across the different STIGIDs broken down by Fortify Priority Order. The status of a STIGID is considered "In Place" when there are no issues reported for a given STIGID.

If the project is missing an HPE Security Fortify Static Code Analyzer (SCA) scan, or the scan contains findings that have not been fixed, hidden or suppressed, STIGID APP5080: CAT II is not considered "In Place". Similarly, if the project is missing an HPE Security Fortify WebInspect scan, or the scan contains any critical findings, STIGID APP5100: CAT II is not considered "In Place".

Name: STIG 3.7

ID: E69C07C0-81D8-4B04-9233-F3E74167C3D2

Each requirement or recommendation identified by the DISA STIG is represented by a STIG identifier (STIGID) which corresponds to a checklist item and a severity code [APP<I>ID</I>: CAT <I>SEV</I>]. DISA STIG identifies several severities with respect to vulnerabilities:
